## 1. Deciding Primes

Show that a language,  $A$ , is decidable iff  $A \leq_m PRIMES$ , where  $PRIMES$  is the set of all prime numbers.

### Solution:

#### 1. If $A$ is decidable, then $A$ is mapping reducible to $PRIMES$

Assume  $A$  is decidable, then there exists a Turing Machine  $M$  that decides  $A$ . We can construct a computable function  $f$  such that for any string  $w$ ,  $w \in A$  iff  $f(w) \in PRIMES$ . We define  $f$  as follows: For each input  $w$ , compute  $M(w)$ . If  $M(w)$  accepts, let  $f(w)$  be a fixed prime number. If  $M(w)$  rejects, let  $f(w)$  be a fixed composite number. Then this function  $f$  is computable as  $M$  is a decider, and thus halts on all inputs.

Thus,  $w \in A \implies f(w)$  is prime, and  $w \notin A \implies f(w)$  is composite. Therefore,  $A$  is mapping reducible to  $PRIMES$ .

#### 2. If $A$ is mapping reducible to $PRIMES$ , then $A$ is decidable

Assume  $A$  is mapping reducible to  $PRIMES$ . Then there exists a computable function  $f$  such that for any string  $w$ ,  $w \in A$  iff  $f(w) \in PRIMES$ .

Since  $PRIMES$  is decidable since there exists algorithms that can decide primes, we can construct a Turing Machine  $PM$  that decides  $A$  as follows:

- (i) On input  $w$ , compute  $f(w)$ .
- (ii) Run the algorithm that decides  $PRIMES$  on  $f(w)$ .
- (iii) If the algorithm accepts, accept. If the algorithm rejects, reject

So the computability of  $f$  ensures that  $PM$  can always compute  $f(w)$  and the decidability of  $PRIMES$  ensures that  $PM$  always halts. Thus,  $PM$  is a decider for  $A$ . Therefore,  $A$  is decidable.

Hence, we can conclude that  $A$  is decidable iff  $A$  is mapping reducible to  $PRIMES$ . ■
